

ABSTRACT

Aims: Atherothrombotic events are influenced by systemic hypercoagulability and fibrinolytic activity. The present study evaluated thrombogenicity indices and their prognostic implications according to disease acuity.

Methods and Results: From the consecutive patients undergoing percutaneous coronary intervention (PCI), those with thrombogenicity indices (n=2,705) were grouped according to disease acuity (acute myocardial infarction [AMI] vs. non-AMI). Thrombogenicity indices were measured by thromboelastography (TEG). Blood samples for TEG were obtained immediately after insertion of the PCI sheath, and TEG tracing was performed within 4 hours post-sampling. Major adverse cardiovascular events (MACE, a composite of cardiovascular death, non-fatal myocardial infarction, and non-fatal stroke) were evaluated for up to 4 years. Compared to non-AMI patients, AMI patients had higher platelet-fibrin clot strength (maximal amplitude [MA]: 66.5 ± 7.8 vs. 65.3 ± 7.2 mm, $P < 0.001$) and lower fibrinolytic activity (clot lysis at 30 minutes [LY_{30}]: $0.9 \pm 1.8\%$ vs. $1.1 \pm 1.9\%$, $P < 0.001$). Index AMI presentation was associated with MA (per 1-mm increase: odds ratio [OR] 1.024; 95% confidence interval [CI] 1.013-1.036; $P < 0.001$) and LY_{30} (per 1% increase: OR 0.934; 95% CI 0.893-0.978; $P = 0.004$). The presence of high platelet-fibrin clot strength ($MA \geq 68$ mm) and low fibrinolytic activity ($LY_{30} < 0.2\%$) was synergistically associated with MACE occurrence. In the multivariable analysis, the combined phenotype of ' $MA \geq 68$ mm' and ' $LY_{30} < 0.2\%$ ' was a major predictor of post-PCI MACE in the AMI group (adjusted hazard ratio [HR] 1.744; 95% CI 1.135-2.679; $P = 0.011$), but not in the non-AMI group (adjusted HR 1.031; 95% CI 0.499-2.129; $P = 0.935$).

Conclusions: AMI occurrence is significantly associated with hypercoagulability and impaired fibrinolysis. Their combined phenotype increases the risk of post-PCI atherothrombotic event only in AMI patients. These observations may support individualized therapy that targets thrombogenicity for better outcomes in patients with AMI.

Key Question

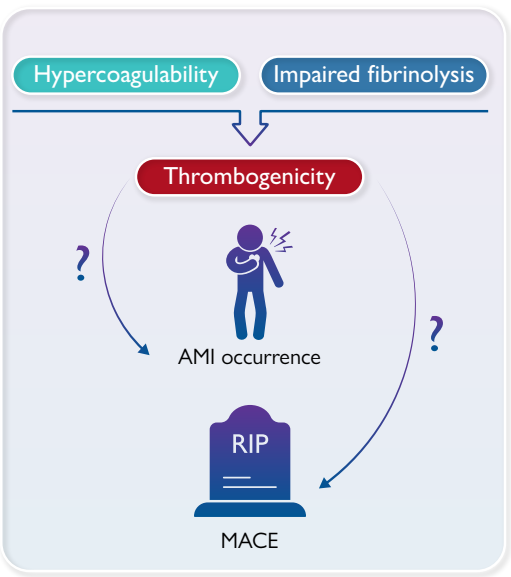

What is the association between thrombogenicity indexes and acute myocardial infarction (AMI) and their impact on long-term outcomes?

Key Finding

Elevated platelet-fibrin clot strength and impaired fibrinolysis were both independently associated with AMI occurrence. Among AMI patients the elevation of both biomarkers was associated with the highest risk of atherothrombotic events during follow up.

Take Home Message

Following percutaneous coronary intervention in AMI patients, individualized application of antithrombotic therapy according to thrombogenicity indexes may reduce the risk of atherothrombotic events.

PCI + TEG (n = 2,705)	AMI occurrence	4-year MACE
	Hypercoagulability MA (per 1 mm increase) OR 1.024 (p < 0.001)	HR 1.029 (p = 0.007)
Fibrinolysis LY ₃₀ (per1% increase)	OR 0.934 (p = 0.004)	HR 0.914 (p = 0.067)
4-year MACE	AMI (n = 1,294)	Non-AMI (n = 1,411)
Thrombogenicity (MA ≥ 68mm and LY ₃₀ < 0.2%)	HR 1.744 (p = 0.011)	HR 1.031 (p = 0.935)

ABSTRACT

Aims: Atherothrombotic events are influenced by systemic hypercoagulability and fibrinolytic activity. The present study evaluated thrombogenicity indices and their prognostic implications according to disease acuity.

Methods and Results: From the consecutive patients undergoing percutaneous coronary intervention (PCI), those with thrombogenicity indices (n=2,705) were grouped according to disease acuity (acute myocardial infarction [AMI] vs. non-AMI). Thrombogenicity indices were measured by thromboelastography (TEG). Blood samples for TEG were obtained immediately after insertion of the PCI sheath, and TEG tracing was performed within 4 hours post-sampling. Major adverse cardiovascular events (MACE, a composite of cardiovascular death, non-fatal myocardial infarction, and non-fatal stroke) were evaluated for up to 4 years. Compared to non-AMI patients, AMI patients had higher platelet-fibrin clot strength (maximal amplitude [MA]: 66.5±7.8 vs. 65.3±7.2 mm, *P*<0.001) and lower fibrinolytic activity (clot lysis at 30 minutes [LY₃₀]: 0.9±1.8% vs. 1.1±1.9%, *P*<0.001). Index AMI presentation was associated with MA (per 1-mm increase: odds ratio [OR] 1.024; 95% confidence interval [CI] 1.013-1.036; *P*<0.001) and LY₃₀ (per 1% increase: OR 0.934; 95% CI 0.893-0.978; *P*=0.004). The presence of high platelet-fibrin clot strength (MA ≥68 mm) and low fibrinolytic activity (LY₃₀<0.2%) was synergistically associated with MACE occurrence. In the multivariable analysis, the combined phenotype of ‘MA ≥68 mm’ and ‘LY₃₀<0.2%’ was a major predictor of post-PCI MACE in the AMI group (adjusted hazard ratio [HR] 1.744; 95% CI 1.135-2.679; *P*=0.011), but not in the non-AMI group (adjusted HR 1.031; 95% CI 0.499-2.129; *P*=0.935).

Conclusions: AMI occurrence is significantly associated with hypercoagulability and impaired fibrinolysis. Their combined phenotype increases the risk of post-PCI atherothrombotic event only

1 INTRODUCTION

2 Although contemporary cardiovascular (CV) treatments including revascularization and guideline-
3 directed medical therapy have improved clinical outcomes in patients with atherosclerotic
4 cardiovascular disease (ASCVD), its associated mortality rate remains unchanged and a
5 considerable number of patients still suffer from recurrent CV events.¹ Abundant clinical evidence
6 has supported the aggressive reduction of low-density lipoprotein cholesterol (LDL-C) in order to
7 reduce CV events. Since achieving guideline-based recommended LDL-C levels fails to guarantee
8 a significant reduction in ASCVD in many patients, further strategies may be required to
9 adequately reduce the remaining CV risk.

10 Treatment guidelines recommend intensified anti-thrombotic treatment in patients with
11 high-risk ischemic features, such as acute myocardial infarction (AMI) and poly-vascular
12 disease,^{2,3} based on the results of randomized controlled trials including the Dual Antiplatelet
13 Therapy (DAPT), Prevention of Cardiovascular Events in Patients with Prior Heart Attack Using
14 Ticagrelor Compared to Placebo on a Background of Aspirin–Thrombolysis in Myocardial
15 Infarction 54 (PEGASUS-TIMI 54), and Cardiovascular Outcomes for People Using
16 Anticoagulation Strategies (COMPASS) trials.^{4,6} This intensified regimen, i.e., the longer-term
17 DAPT administration and the addition of vascular-dose rivaroxaban to aspirin, has significantly
18 reduced the risk of atherothrombotic events compared with aspirin monotherapy, however, the risk
19 of bleeding events has increased.

20 Following percutaneous coronary intervention (PCI), the activation of platelet and
21 coagulation pathways followed by atherosclerotic vascular injury is fundamental to the
22 development of acute and chronic CV events.⁷ However, most post-PCI risk stratifications
23 addressing anti-thrombotic agents have focused on antiplatelet strategy in addition to clinical and

1
2
3
4
5
6
7
8
9
10
11
12 1 procedural factors.^{8,9} The lack of reliable laboratory tests for measuring the clot formation-lysis
13
14 2 process leads to an underestimate of its effects on clinical prognosis. Therefore, we have an unmet
15
16 3 need for reliable biomarkers or surrogates for this biological issue. For this purpose, there are
17
18 4 several available candidates such as the global haemostasis assays which use native whole blood
19
20 5 (e.g., thromboelastography [TEG], global thrombosis test [GTT]) or plasma (e.g., plasma
21
22 6 turbidimetric assay).¹⁰ The TEG assay uses citrated whole blood to measure clot formation under
23
24 7 a low shear rate, whereas GTT uses a non-anticoagulated blood sample under a high shear rate.
25
26 8 There have been conflicting results regarding the association between clinical outcomes and
27
28 9 parameters from these haemostasis assays.¹⁰⁻¹³ After PCI, the maximum amplitude (MA, platelet-
29
30 10 fibrin clot formation) in the TEG assay has been mainly correlated with worse outcomes,¹² whereas
31
32 11 lysis time (LT, fibrinolysis activity) in the GTT assay can predict clinical prognosis.¹¹

33
34 12 To date, clinical evidence for the TEG assay has been modest in size and included selected
35
36 13 patients with relatively short-term follow-ups. We sought to evaluate its clinical usefulness in a
37
38 14 large-scale high-risk population that included ASCVD patients undergoing PCI by assessing: 1)
39
40 15 thrombogenicity indices in patients who presented with and without AMI; and 2) the prognostic
41
42 16 implications of thrombogenicity indices on long-term major adverse CV events (MACE) after PCI.

43 17 44 45 18 **METHODS**

46 47 19 ***Study Population***

48
49 20 The study population was derived from the multicenter, prospective, observational Gyeongsang
50
51 21 National University Hospital (G-NUH) registry (clinicaltrials.gov identifier, NCT04650529).¹⁴
52
53 22 The G-NUH registry enrolled consecutive patients with significant coronary artery disease (CAD)

1 who underwent PCI in two distinct tertiary referral hospitals between January 2010 and November
2 2018, and included systematically evaluated multiple haemostatic, vascular, and physiologic
3 parameters (**Figure 1**). From the 5,080 total patients, we included those who had undergone pre-
4 PCI TEG measurement. A total of 2,375 patients were excluded due to duplicate patient data
5 (readmission or staged procedure, n = 622), due to follow-up loss (n = 112), and a lack of TEG
6 data, which included not available blood sampling (e.g., cardiogenic shock, n = 191), oral
7 anticoagulation before sampling (n = 330), and off-hour visit (weekdays from 6 PM to 9 AM,
8 weekends, and holidays) of technicians hired for haemostatic measurement (n = 1,120). There
9 were no significant differences in the baseline characteristics between included and excluded
10 patients (Table S1).

11 The Institutional Review Board of the respective hospitals approved the study protocol and
12 waived the requirement for written informed consent for the access to an institutional registry. The
13 study protocol was in accordance with the Good Clinical Practice Guidelines and the Declaration
14 of Helsinki.

15
16 ***Patient Management and Procedures***

17 Patients were treated according to standard practice at both hospitals, based on the current
18 guidelines.^{2,15-17} The choice of treatment strategy (stent implantation and medication choice) was
19 left to the operator's discretion. All patients were recommended indefinite aspirin and clopidogrel
20 or other P2Y₁₂ inhibitor treatment, such as prasugrel or ticagrelor. Treatment duration and choice
21 of P2Y₁₂ inhibitor was left to the operator's discretion in accordance with the guidelines and the
22 patients' individual bleeding risks as perceived by the treating physician.

11
12 1 Demographic features and CV risk factors were collected through patient interviews or by
13
14 2 reviewing of medical records. During hospitalization, findings of coronary angiography and
15 3 detailed procedural characteristics of PCI as well as information on discharge medications were
16 4 collected.
17
18
19 5

21 6 ***Thromboelastography (TEG) Measurement***

22
23 7 According to the prespecified protocol,¹⁴ blood samples for TEG were drawn into Vacutainer tubes
24
25 8 containing 3.2% trisodium citrate (Becton Dickinson, Franklin Lakes, NJ, USA) from the arterial
26
27 9 sheath immediately after sheath insertion for coronary angiography, and TEG tracing was
28
29 10 performed within 4 hours of sampling by a dedicated technician. Periprocedural heparin for the
30
31 11 prevention of thrombosis was administered after blood sampling for TEG measurement. For
32 12 haemostatic assessment, the TEG[®] 5000 Hemostasis Analyzer System (Haemonetics Corp,
33
34 13 Braintree, MA, USA) with automated analytical software was used.¹⁸ Briefly, 500 µL of citrated
35
36 14 blood was mixed with kaolin by inversion, and 340 µL of the activated blood was then transferred
37
38 15 to the reaction cup, to which 20 µL of 200 mmol/L calcium chloride was added. In heparin-
39
40 16 pretreated cases, the classic TEG kit and the TEG kit with added heparinase (hTEG) were
41
42 17 simultaneously used to evaluate the neutralizing effect of heparinase. A stationary pin was
43 18 suspended into an oscillating cup that contained the whole blood sample. As the blood clots, it
44
45 19 links the pin to the cup. Pin movement is converted into an electrical signal by a transducer and is
46
47 20 interpreted by the computer which creates a tracing.

48
49 21 Reaction time (R, in minutes), a representative value of enzymatic clotting, is the time from
50
51 22 the start of the sample run to the point of the initial clot formation corresponding to an amplitude
52
53 23 of 2 mm of the TEG tracing. K (in minutes) is a measure of the time required to reach a 20 mm

1
2
3
4
5
6
7
8
9
10
11
12 1 clot strength from time point R. Angle (in degrees) is reflective of the fibrinogen activity and is
13
14 2 the angle degree formed by the tangent line to the TEG tracing measure at the R time point. Kaolin-
15 3 induced maximum amplitude (MA, in millimeters) represents the maximum platelet-fibrin clot
16
17 4 strength (PFCS). LY₃₀ is the percentage of the clot that has lysed 30 minutes after the MA time
18
19 5 point and indicates the level of fibrinolytic activity.
20
21 6

22
23 7 ***Study Endpoint, Definitions, and Follow-up***

24
25 8 The primary endpoint was the MACE, which was defined as a composite occurrence of CV death,
26
27 9 spontaneous MI, and non-fatal stroke for up to 4 years after PCI. All endpoints were defined
28
29 10 according to the Academic Research Consortium definitions.¹⁹ All deaths were considered CV
30
31 11 unless a definitive non-CV cause was identified. Spontaneous MI (or Type 1 MI) was defined as
32
33 12 the recurrence of symptoms with the presence of electrocardiographic changes, or imaging
34
35 13 evidence of new loss of viable myocardium or new regional wall motion abnormalities in
36
37 14 association with a rise in cardiac biomarker levels above the upper limit of normal. Peri-procedural
38
39 15 MI was not included as a clinical outcome. Stroke was defined as evidence of a neurological deficit
40
41 16 requiring hospitalization, with clinically documented brain lesions on computed tomography or
42
43 17 magnetic resonance imaging confirmed by a neurologist. All clinical events were evaluated by an
44
45 18 independent event adjudicating committee. Patients were routinely followed up by outpatient visits
46
47 19 or by telephone at 1, 6, and 12 months after the index procedure, and annually thereafter.
48

49 21 ***Statistical Analysis***

50
51 22 All categorical variables are presented as numbers and relative frequencies (percentage).
52
53 23 Continuous variables are presented as means and standard deviations, or as medians with first and

1 third quartiles, according to their distribution, which has been checked by Kolmogorov-Smirnov
2 test and a visual inspection of the Q-Q plots. Differences between groups were assessed using the
3 chi-square test for categorical variables and the Student's *t*-test or the Mann-Whitney U test for
4 continuous variables. For the multiple-group comparisons according to the MA and LY₃₀,
5 continuous variables were tested using the analysis of variance to test for differences.

6 The optimal cut-off values of MA and LY₃₀ associated with index MI presentation were
7 calculated using receiver-operating characteristic (ROC) curves to maximize the sensitivity and
8 specificity. To evaluate the clinical impact of MA and LY₃₀ on the presence of index AMI,
9 univariable and multivariable logistic regression analyses were performed. The multivariable
10 model was constructed using all variables with a significance of $P < 0.1$ in the univariable analyses.
11 The final multivariable model was constructed using backward elimination to identify the best
12 Akaike's information criterion, and odds ratios (ORs) and 95% confidence intervals (CIs) were
13 identified.

14 The associations between MA or LY₃₀ as continuous variables and the risk of 4-year
15 MACE were graphically presented with a restricted cubic spline with three degrees of freedom.²⁰
16 Cumulative event rates were estimated with the Kaplan-Meier method and compared using the
17 log-rank test. A Cox proportional hazard regression model was used to calculate hazard ratios
18 (HRs) and 95% CIs. The assumption of proportionality was assessed graphically by the log-minus-
19 log plot and was also tested by Schoenfeld residuals. Multivariable Cox proportional hazard
20 models were constructed using variables with $P < 0.1$ in univariable analyses with backward
21 elimination based on an information criterion. The final model included thrombogenicity,
22 diagnosis of AMI, age, sex, current smoking, hypertension, diabetes mellitus, dyslipidaemia,
23 chronic kidney disease, previous PCI, previous stroke, high sensitivity C-reactive protein (CRP)

level, potent P2Y₁₂ inhibitor, beta blocker, angiotensin blocker, and statin. The incremental prognostic value of TEG values was evaluated by comparing Harrell's c-index, category-free net reclassification index (NRI), and integrated discrimination index (IDI).

Statistical analyses were performed using SPSS version 25 for Windows (SPSS-PC, Chicago, IL, USA), and R version 3.6.2 (R Foundation for Statistical Computing, Vienna, Austria). All tests were two-tailed, and $P < 0.05$ was considered statistically significant.

RESULTS

Baseline Characteristics

A total of 2,705 patients were identified for the current analysis, and grouped into two cohorts: AMI (n = 1,294, 47.8%) and non-AMI (n = 1,411, 52.2%) (Figure 1). Table 1 shows the baseline characteristics of the study population according to the index diagnosis of AMI. Patients who presented with AMI were older and had a higher incidence of current smoking, dyslipidaemia, and peripheral arterial disease than those without AMI. Conversely, the non-AMI group had a higher incidence of diabetes mellitus, hypertension, and previous PCI. Patients in the AMI group had higher levels of white blood cell count, haemoglobin and LDL-C, and a lower left ventricular ejection fraction.

Although there were no significant differences in procedural methods between the groups, AMI patients were treated with a fewer number of stents compared with non-AMI patients. The AMI group was more frequently treated with potent P2Y₁₂ inhibitors. Beta blockers, angiotensin receptor blockers, and statins were also more frequently prescribed in the AMI than in the non-AMI group.

Association Between Thrombogenicity Indices and Index Presentation of Disease

Table 2 shows TEG measurements according to the index presentation of disease acuity. PFCS was significantly higher in patients presenting with AMI (MA: 66.5 ± 7.8 vs. 65.3 ± 7.2 mm; $P < 0.001$). In addition, LY₃₀ was significantly lower in the AMI group compared with the non-AMI group (0.9 ± 1.8 vs. 1.1 ± 1.9 mm; $P < 0.001$). When we stratified the AMI phenotype into ST-segment elevation vs. non-ST-segment elevation, patients with ST-segment elevation showed an enhanced thrombogenic property including a higher level of PFCS (MA: 67.1 ± 7.4 vs. 65.8 ± 8.3 mm; $P < 0.001$) than those with non-ST-segment elevation AMI (**Table S2**).

By multivariable analysis (**Table 3**), both MA (every 1 mm increase: OR, 1.024; 95% CI, 1.013-1.036; $P < 0.001$) and LY₃₀ (every 1% increase: OR, 0.934; 95% CI, 0.893-0.978; $P = 0.004$) were independently associated with index AMI presentation, with a modest to good association (c-statistics = 0.69). **Figures S1** and **S2** show the optimal cut-offs of MA and LY₃₀ for the index presentation of AMI, respectively. In the present analysis, ‘MA ≥ 68 mm’ indicated hypercoagulability phenotype and ‘LY₃₀ $< 0.2\%$ ’ indicated an impaired fibrinolysis phenotype. The AMI patients had a higher prevalence of hypercoagulability (44.9% vs. 35.4%; $P < 0.001$) and impaired fibrinolytic activity (53.7% vs. 42.9%; $P < 0.001$) compared with the non-AMI patients.

Prognostic Implications of Thrombogenicity Indices for Long-term MACE

As a continuous variable, MA was significantly associated with the MACE rate at 4 years (HR, 1.029; 95% CI, 1.008-1.051; $P = 0.007$) (**Figure 2A**). LY₃₀ showed a numerical trend of a protective effect against 4-year MACE (HR, 0.914; 95% CI, 0.831-1.006; $P = 0.067$) (**Figure 2B**). When we compared clinical outcomes according to binary classification of MA (≥ 68 vs. < 68 mm)

and LY₃₀ (< 0.2% vs. ≥ 0.2%), both hypercoagulability ('MA ≥ 68 mm': HR; 1.707; 95% CI, 1.265-2.305; *P* < 0.001) and impaired fibrinolytic activity ('LY₃₀ < 0.2%': HR, 1.512; 95% CI, 1.118-2.045; *P* = 0.007) were associated with an increased risk of 4-year MACE (**Figure 3**). When considering the presence of hypercoagulability and impaired fibrinolytic activity simultaneously (**Table S3**), patients with 'MA ≥ 68 mm' and 'LY₃₀ < 0.2%' (hypercoagulability with impaired fibrinolytic activity) had an increased risk of 4-year MACE (31.2% vs. 10.7%: adjusted HR, 1.781; 95% CI, 1.130-2.808; *P* = 0.012) compared with those with 'MA < 68 mm' and 'LY₃₀ ≥ 0.2%' (normal coagulability and normal fibrinolytic activity) (**Figure 4** and **Table S4**).

The incremental prognostic value of thrombogenicity (hypercoagulability with impaired fibrinolytic activity) was compared with the clinical variable model. The final model, which included thrombogenicity, showed an increased discrimination and reclassification ability (c-index 0.756, *P* < 0.001; NRI 0.701, *P* < 0.001; IDI 0.059, *P* < 0.001) (**Figure S3**).

Differential Impact of Thrombogenicity Indices According to Index Disease Acuity

There were several differences in the risk of 4-year MACE among the groups when classified by thrombogenicity indices and index disease acuity (overall log-rank *P* < 0.001) (**Figure 5**). Index AMI phenotype with heightened thrombogenicity ('MA ≥ 68 mm' + 'LY₃₀ < 0.2%') had the greatest risk of 4-year MACE. Heightened thrombogenicity did not increase the risk of MACE in non-AMI patients (HR, 1.031; 95% CI, 0.499-2.129; *P* = 0.935), whereas it did have a significant prognostic implication in AMI patients (HR, 1.744; 95% CI, 1.135-2.679; *P* = 0.011) (**Table 4**).

1 The current study is the largest analysis evaluating the relationship of hypercoagulability and
2 impaired fibrinolysis by TEG assessment according to disease acuity, and its influence on long-
3 term outcomes after PCI. The present analysis demonstrated that: 1) elevated levels of platelet-
4 fibrin clot strength and low fibrinolysis activity measured by TEG were both independently
5 associated with the index AMI presentation; and 2) each marker was significantly associated with
6 worse clinical prognoses and their combined occurrence was associated with the highest risk of
7 MACE in AMI patients undergoing PCI (Structured Graphical Abstract).

8 The balance between prothrombotic and fibrinolytic factors is a key determinant in the
9 development of ASCVD events.²¹ In the Multi-Ethnic Study of Atherosclerosis (MESA) cohort,
10 thrombotic biomarkers, such as fibrinogen and factor VIII, were associated with a higher risk of
11 ASCVD events, while fibrinolytic factors, such as oxidized phospholipid bound to plasminogen,
12 were associated with a lower risk of ASCVD events, even after a multivariate analysis of
13 traditional CV risk factors.²² These assays, however, may not be appropriate for diagnosis and risk
14 stratification in individual patients due to their variability and complexity.²³ Therefore, there have
15 been efforts to use global haemostasis tests for measuring thrombosis and fibrinolysis in patients
16 with CAD. Previous studies demonstrated that MA measured by TEG was correlated with the
17 adenosine diphosphate (ADP)-induced platelet aggregation, coagulation factors (e.g., von
18 Willebrand factor and fibrinogen), and inflammation markers (e.g., CRP and interleukin-8), which
19 have been considered meaningful predictors of ASCVD development.^{12,24-26} The results of the
20 Thrombotic RIsK Progression (TRIP) study demonstrated that a distinct pathophysiological state
21 of heightened platelet function, hypercoagulability and inflammation marks the presence of
22 unstable ASCVD requiring intervention. In this study, a significant relationship was found
23 between two important biologic markers, PFCS and CRP, as well as between them and other

1 biomarkers such as fibrinogen, von Willebrand factor, and plasminogen activator inhibitor (PAI)-
2 1.²⁷ Patients with poly-vascular disease who have synchronous CAD and peripheral arterial disease
3 had significantly higher MA and CRP levels compared with CAD patients with normal ankle-
4 brachial indexes.¹⁸

5 Endogenous fibrinolysis may have a protective role in attenuating the occurrence of
6 coronary events.²⁸⁻³⁰ Saraf et al. showed that LT measured by GTT, a marker of endogenous
7 thrombolysis, was prolonged in patients with acute coronary syndrome (ACS) compared to healthy
8 patients.³¹ In addition, AMI patients who presented with spontaneous ST-segment resolution
9 before PCI had more rapid fibrinolytic activity than those who did not.¹¹ Sumaya et al. studied the
10 clinical impact of plasma clot LT and maximum turbidity among ACS patients, and found that the
11 resistance of fibrin clots to lysis was independently associated with adverse clinical events.¹³

12 Furthermore, both hypercoagulability and endogenous fibrinolysis were significant
13 predictors of clinical outcomes in previous studies. Farag et al. showed that LT measured by GTT
14 could identify the high ischemic phenotype in patients presenting with ST-segment elevation MI.¹¹
15 In their study, prolonged LT was highly predictive of recurrent MACE during a 1-year follow-up.
16 Similarly, Jeong et al. evaluated the relationship between TEG MA and high platelet reactivity
17 (HPR) in PCI-treated patients. A high MA was associated with a higher rate of HPR phenotype,
18 and both parameters were associated with an increased risk of 2-year MACE.³² Gurbel et al.
19 investigated the prognostic implication of MA in CAD patients undergoing PCI.³³ ‘MA > 69 mm’
20 was a significant independent predictor of first ischemic events during their 3-year follow-up.
21 Kang et al. evaluated the association between thrombogenicity and coronary microvascular
22 dysfunction (CMD, defined as an index of microcirculatory resistance > 40 U) in AMI patients.¹⁴
23 ‘MA ≥ 68 mm’ was significantly associated with post-procedural CMD in the culprit lesion, and

1 as well as with a higher rate of MACE. In the present study, we enrolled 2,705 patients who
2 underwent pre-PCI global haemostasis profiling by TEG, and evaluated the clinical outcomes
3 during a 4-year clinical follow-up. From our comprehensive analysis, we were able to confirm the
4 close link of platelet-fibrin clot strength and endogenous fibrinolysis with the progression of
5 ASCVD, and the differential impact of these markers on long-term atherothrombotic events
6 according to the index disease acuity following PCI. In the current analysis, hypercoagulability
7 and impaired fibrinolysis were associated with MACE in the AMI group, but not in the non-AMI
8 group. AMI patients have a high-risk profile, which is associated with combined CV risks and
9 comorbidities, as well as vulnerable blood property. The association between thrombogenicity and
10 clinical events is likely closer in the AMI phenotype. Therefore, potent control of coagulation-
11 fibrinolysis activity would be required in these patients to prevent the recurrence of
12 atherothrombotic events.

13 However, interpreting the results from global haemostasis tests might require caution.
14 Spinhakis et al. showed the difference in GTT and TEG measurements in evaluating fibrinolysis
15 after anticoagulation treatment.³⁴ They found a discrepancy between the GTT and TEG parameters,
16 namely, that the effect of apixaban on endogenous fibrinolysis was only observed with the GTT
17 assay. In general, the GTT technique simulates high-shear circumstances, whereas the TEG
18 technique assesses the global viscoelastic properties under low-shear circumstances.^{30,34} Therefore,
19 TEG measurement may have some limitations in the evaluation of the function of fibrinolysis
20 among CAD patients.

21 The present study has demonstrated again that high-risk patients with diabetes, chronic
22 kidney disease, and enhanced inflammation have high level of thrombogenicity, especially those
23 presenting with both hypercoagulability and impaired endogenous fibrinolysis.³⁵⁻³⁸ Interestingly,

1
2
3
4
5
6
7
8
9
10
11
12 1 thrombogenicity was found to be associated with long-term clinical outcomes after index PCI
13
14 2 among AMI patients, even after guideline-directed medical therapy. These findings suggest that
15 3 platelet-fibrin-plasmin interaction can be a future target for individualized therapy for improving
16 4 the clinical outcomes in AMI patients. AMI patients with thrombogenicity might be the best
17 5 anticoagulant therapy candidates when looking to maximize net benefit. Although other
18 6 haemostasis assays have several limitations such as limited availability and the need for well-
19 7 trained personnel,¹³ TEG is a reliable test that has been in clinical practice for a long time. The
20 8 updated TEG 6S system is fully automated with small variability,³⁹ and is relatively unbound by
21 9 the requirement for ample personnel resources. Therefore, TEG may be a relevant modality for
22 10 assessing the residual ischemic risk and stratifying the high-risk AMI patients after PCI in order
23 11 to determine their long-term clinical prognoses.

32
33
34 13 ***Limitations***

35
36 14 This study had several limitations. First, this was a prospective observational study. Although
37 15 about 3,000 patients were consecutively enrolled in the current analysis, we could not exclude the
38 16 possibility of selection bias or other systematic confounders. Concomitant medical therapies might
39 17 have affected the clinical outcomes; however, this could not be fully evaluated in the current
40 18 analysis since there were no significant differences in prescribed medications according to the
41 19 thrombogenicity. Second, although we have reported relatively long-term clinical outcomes, the
42 20 mean duration of follow-up was roughly 2 years. Third, our study is hypothesis-generating rather
43 21 than confirmative. However, we believe that our findings regarding the cut-offs of this laboratory
44 22 assay may present an important background for personalized antithrombotic therapy in future
45 23 studies. Further research may be needed to establish the clinical usefulness of TEG measurement
46

2
3
4
5
6
7
8
9
10
11
12 1 in real-world practice. Fourth, it is known that external factors including lipid modification can
13
14 2 affect endogenous clot characteristics.⁴⁰ To minimize these effects, blood sampling was timely
15
16 3 performed on the same day of the PCI. However, we could not fully exclude the effects of these
17
18 4 external factors on the TEG measurements. Fifth, the decision of performing PCI in stable CAD
19
20 5 patients by the attending physician on the basis of imaging or invasive coronary physiologic tests
21
22 6 for intermediate stenosis, which might not fully reflect the current practice. Sixth, there is a concern
23
24 7 regarding whether the MA value obtained by the TEG is an actionable indicator. Several studies
25
26 8 have already shown the relationship between the use of oral anticoagulants and the reduction of
27
28 9 MA values,^{41,42} which requires further laboratory evidence. Finally, we only collected clinically
29
30 10 available laboratory data. Therefore, there is a possibility of missing crucial biomarkers affecting
31
32 11 the TEG value and its prognostic implications.¹³

36 14 ***Conclusions***

37
38 15 Heightened thrombogenicity evaluated by TEG-defined hypercoagulability and impaired
39
40 16 fibrinolytic activity was associated with the occurrence of index AMI at the time of PCI. Despite
41
42 17 guideline-recommended intensive medical therapy, heightened thrombogenicity was found to be
43
44 18 an important predictor of long-term adverse clinical outcomes.

Figure Legends

Figure 1. Study Flow

Abbreviations: AMI = acute myocardial infarction; G-NUH = Gyeongsang National University Hospital; LY₃₀ = percentage of the clot that has lysed 30 minutes after the time of maximum amplitude; MA = maximum amplitude; PCI = percutaneous coronary intervention; TEG = thromboelastography

Figure 2. Association Between MACE at 4 Years and TEG Parameters

Spline curves showed association between (A) MA or (B) LY₃₀ and MACE at 4 years. Abbreviations: CI = confidence interval; HR = hazard ratio; MACE = major adverse cardiovascular events; other abbreviations as in Figure 1.

Figure 3. Comparison of 4-Year MACE According to TEG parameters

Comparison of cumulative incidence and Kaplan-Meier curves of MACE at 4 years according to (A) hypercoagulability and (B) impaired fibrinolytic activity. Abbreviations as in Figures 1 and 2.

Figure 4. Comparison of 4-Year MACE According to Hypercoagulability and Impaired Fibrinolytic Activity

Comparison of cumulative incidence and Kaplan-Meier curves of MACE at 4 years according to the 3 groups classified by MA and LY₃₀; 1) MA <68 mm and LY₃₀ ≥0.2%, 2) MA ≥68 mm or LY₃₀ <0.2%; and 3) MA ≥68 mm and LY₃₀ <0.2%. Abbreviations as in Figures 1 and 2.

Figure 5. Comparison of 4-Year MACE According to Thrombogenicity and AMI Acuity

Comparison of cumulative incidence and Kaplan-Meier curves of MACE at 4 years according to the 4 groups by thrombogenicity and index AMI presentation. Abbreviations as in Figures 1 and 2.

The association between thrombogenicity and AMI occurrence, and their prognostic implications for long-term cardiovascular outcomes were investigated.

Abbreviations: AMI = acute myocardial infarction; HR = hazard ratio; LY₃₀ = percentage of the clot that has lysed 30 minutes after the time of maximum amplitude; MA = maximum amplitude; MACE = major adverse cardiovascular events; OR = odds ratio; PCI = percutaneous coronary intervention; TEG = thromboelastography.

Hypertension	0.749 (0.644-0.871)	<0.001	-	-
Dyslipidemia	1.781 (1.528-2.076)	<0.001	1.703 (1.440-2.014)	<0.001
Previous PCI	0.491 (0.393-0.615)	<0.001	0.602 (0.475-0.764)	<0.001
Hemoglobin (every 1 g/dL increase)	1.129 (1.087-1.173)	<0.001	1.161 (1.107-1.217)	<0.001

Data are expressed as number of events (%). The c-statistics of multivariable model was 0.69.

* Multivariable logistic regression model was constructed using variables with *P* <0.1 in univariable analyses.

Abbreviations: AMI = acute myocardial infarction; CI = confidence interval; LY₃₀ = percentage of the clot that has lysed 30 minutes after the time of maximum amplitude; MA = maximum amplitude; PCI = percutaneous coronary intervention.

Table 4. Prognostic Implication of Thrombogenicity Indices According to Index Disease Acuity

	Cumulative incidence	Adjusted HR* (95% CI)	<i>P</i> value	Adjusted HR* (95% CI)	<i>P</i> value
MACE (Cardiovascular death, MI, Stoke)					
1. Non-AMI & No Thrombogenicity†	11.7% (54)	Reference			
2. Non-AMI & Thrombogenicity†	15.2% (13)	1.031 (0.499-2.129)	0.935		
3. AMI & No Thrombogenicity†	18.0% (66)	1.769 (1.173-2.669)	0.007	Reference	
4. AMI & Thrombogenicity†	45.7% (39)	2.451 (1.541-3.899)	<0.001	1.744 (1.135-2.679)	0.011
Cardiovascular death					
1. Non-AMI & No Thrombogenicity†	3.2% (22)	Reference			
2. Non-AMI & Thrombogenicity†	6.5% (7)	1.228 (0.446-3.378)	0.691		
3. AMI & No Thrombogenicity†	7.6% (24)	2.054 (1.053-4.007)	0.035	Reference	
4. AMI & Thrombogenicity†	7.6% (17)	4.032 (1.899-8.561)	0.001	2.062 (1.026-4.143)	0.042
MI					
1. Non-AMI & No Thrombogenicity†	3.9% (20)	Reference			
2. Non-AMI & Thrombogenicity†	2.1% (4)	0.360 (0.047-2.756)	0.325		
3. AMI & No Thrombogenicity†	11.6% (42)	3.302 (1.737-6.275)	<0.001	Reference	
4. AMI & Thrombogenicity†	31.7% (20)	4.430 (2.096-9.365)	<0.001	1.473 (0.828-2.623)	0.188
Stroke					
1. Non-AMI & No Thrombogenicity†	5.1% (14)	Reference			
2. Non-AMI & Thrombogenicity†	5.0% (3)	1.339 (0.372-4.823)	0.655		
3. AMI & No Thrombogenicity†	7.8% (14)	1.130 (0.486-2.626)	0.777	Reference	
4. AMI & Thrombogenicity†	13.8% (9)	1.837 (0.702-4.806)	0.215	2.281 (0.887-5.870)	0.087
BARC type 3 or 5 bleeding					
1. Non-AMI & No Thrombogenicity†	4.2% (26)	Reference			
2. Non-AMI & Thrombogenicity†	2.5% (4)	0.883 (0.297-2.626)	0.823		
3. AMI & No Thrombogenicity†	7.9% (28)	1.985 (1.044-3.776)	0.037	Reference

---------------------------	----------	---------------------	-------	---------------------	-------

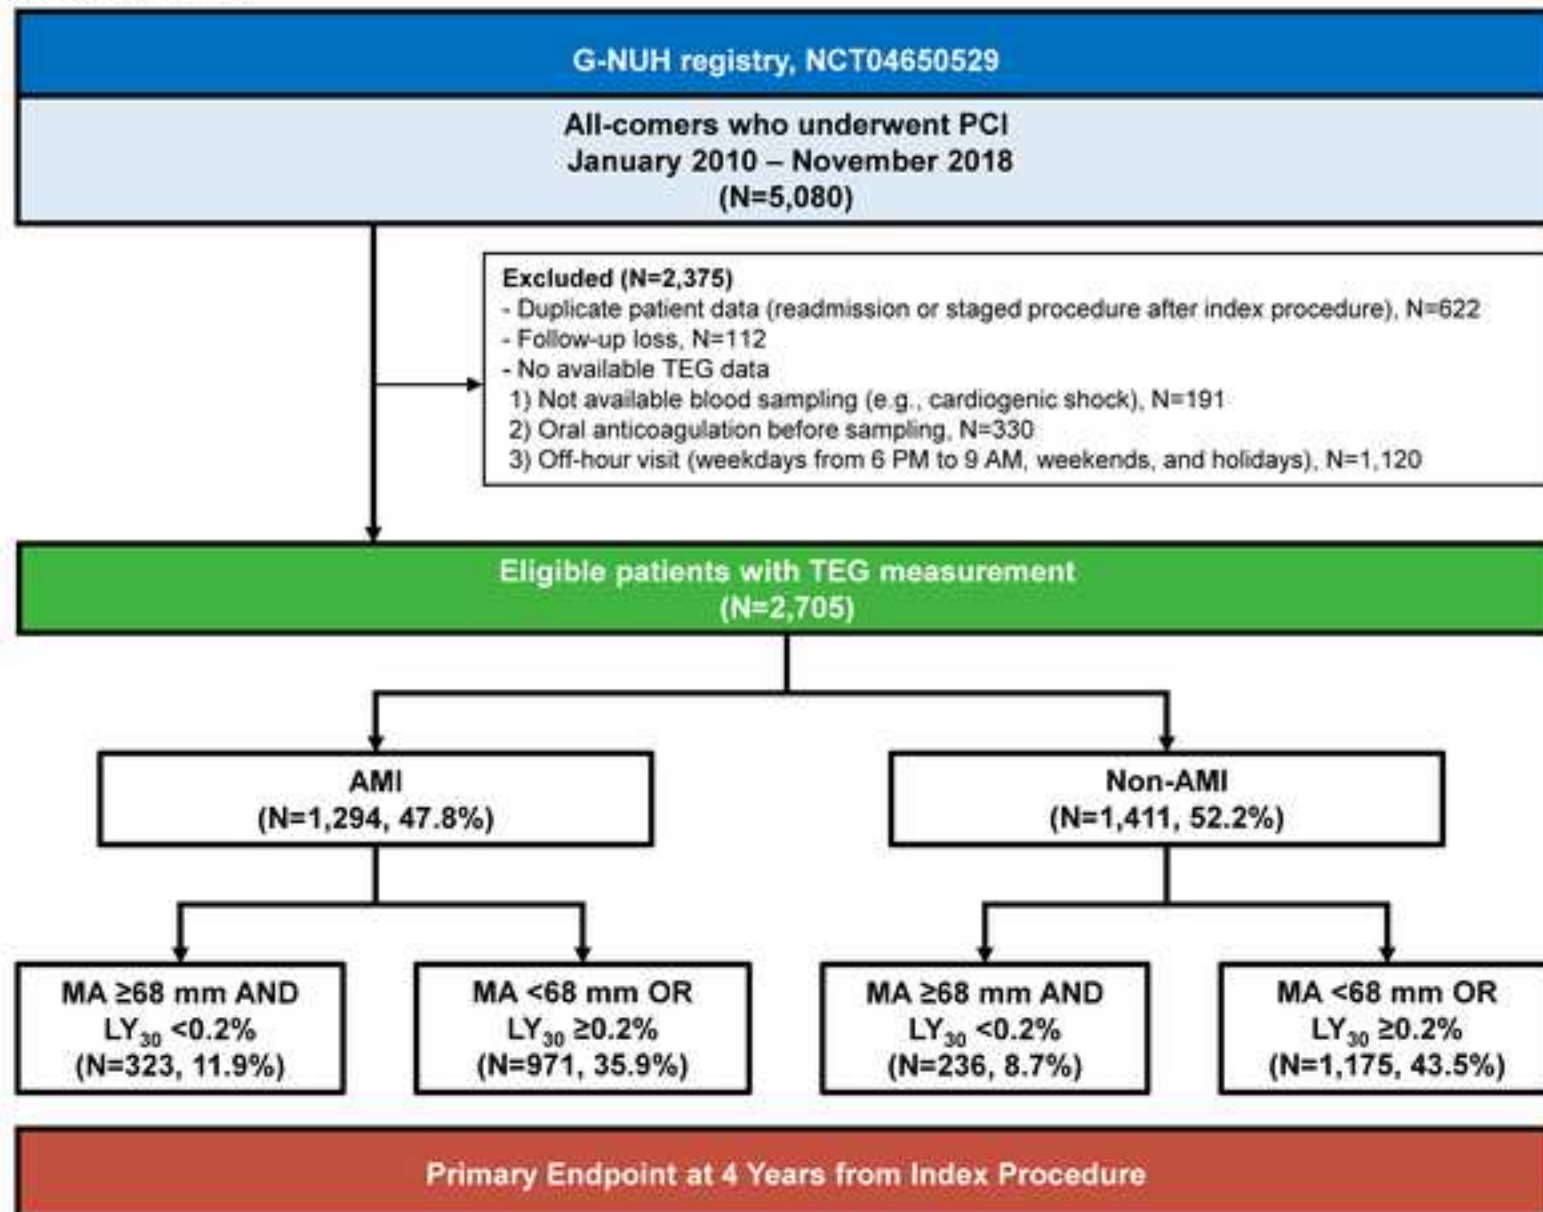

The cumulative incidence of clinical outcomes is presented as Kaplan-Meier estimates. The number of patients with specific events is also presented in parentheses.

* Multivariable analysis after adjusting for age, sex, current smoking, hypertension, diabetes mellitus, dyslipidemia, chronic kidney disease, previous PCI, previous stroke, high sensitivity C-reactive protein level, potent P2Y₁₂ inhibitor, beta blocker, angiotensin blocker, and statin.

† Defined as MA ≥68 mm and LY₃₀ <0.2%

Abbreviations: BARC = Bleeding Academic Research Consortium; CI = confidence interval; HR = hazard ratio; MACE = major adverse cardiac event; MI = myocardial infarction.

Figure 1. Study Flow

Primary Endpoint: A composite of cardiovascular death, non-fatal myocardial infarction, and non-fatal stroke

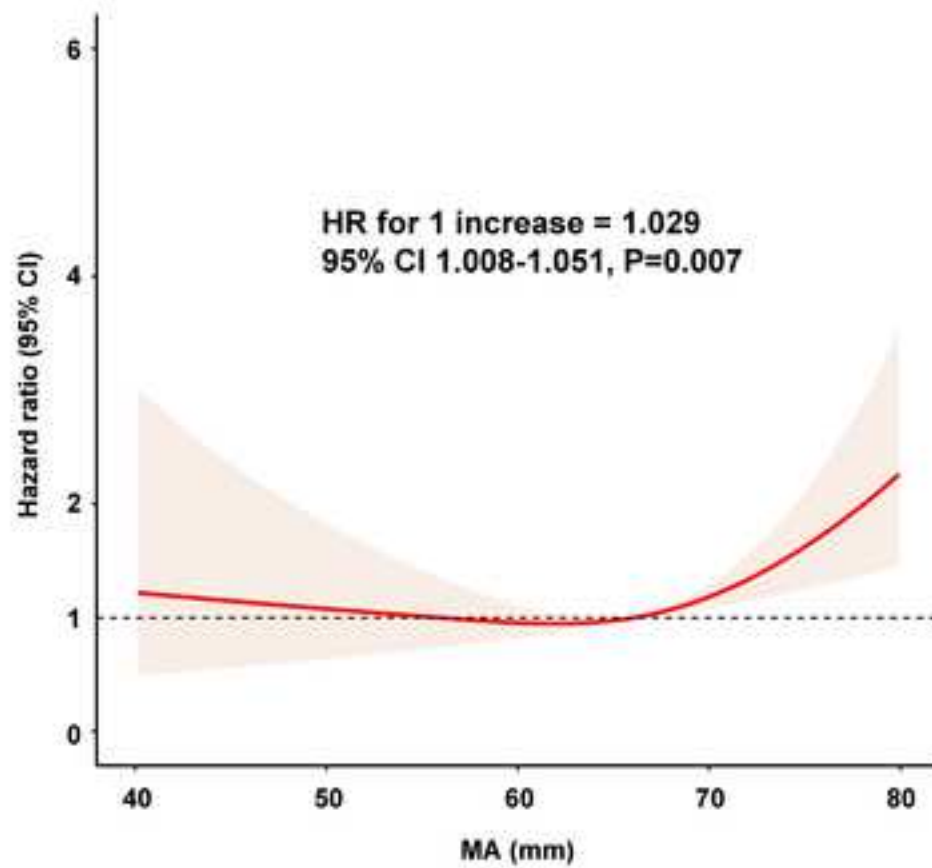

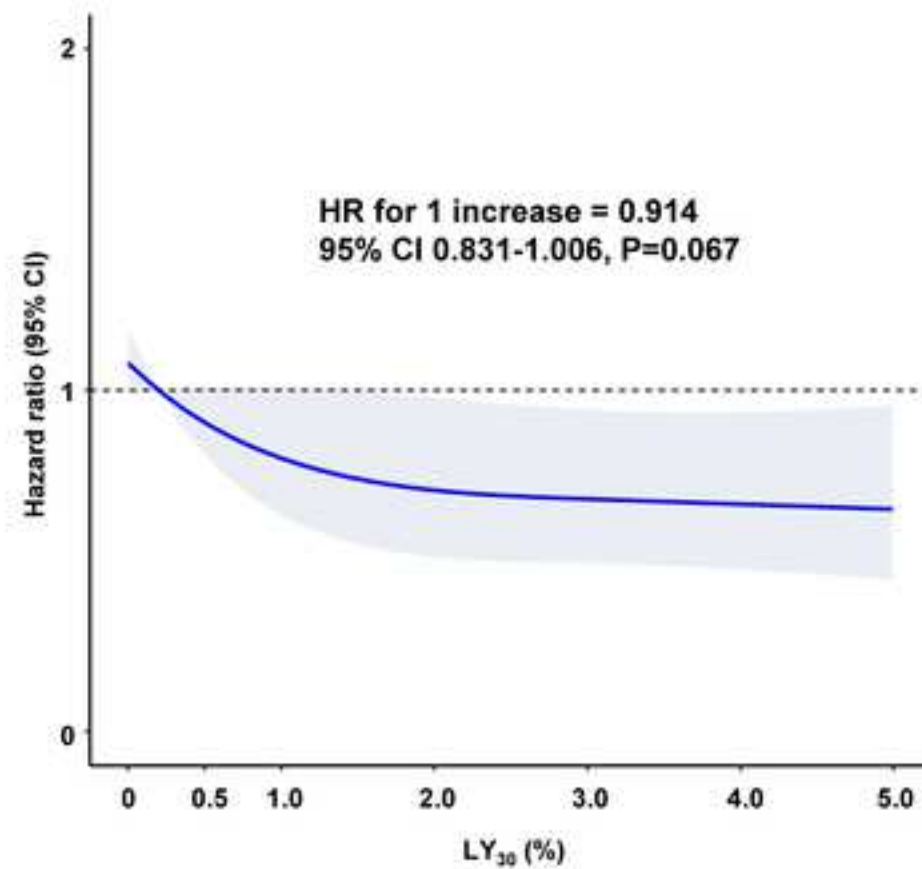

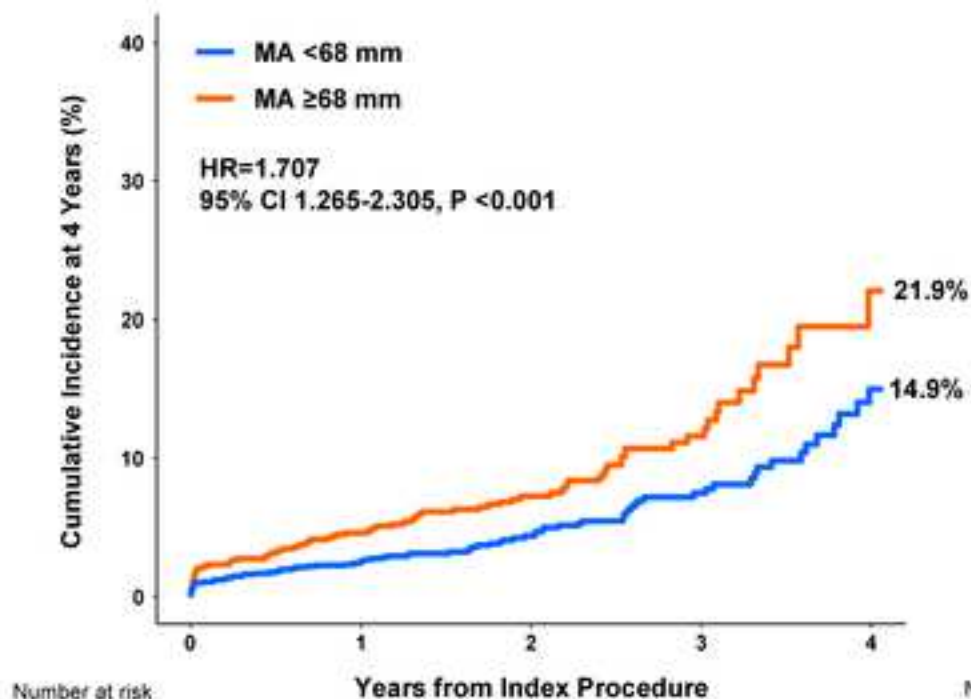

Figure 2. Association Between MACE at 4 Years and TEG Parameters**A. MA****B. LY₃₀**

Figure 3. Comparison of 4-Year MACE According to TEG parameters**A. Hypercoagulability (MA \geq 68 mm vs. MA <68 mm)**

MA <68 mm	1624	1190	653	297	91
MA \geq 68 mm	1081	766	452	160	29

B. Impaired Fibrinolytic Activity (LY₃₀ <0.2% vs. LY₃₀ \geq 0.2%)

LY ₃₀ \geq 0.2%	1404	1038	588	258	70
LY ₃₀ <0.2%	1301	918	517	199	50

SUPPLEMENTAL MATERIAL

This appendix has been provided by the authors to give readers additional information about their work.

Supplemental Tables

Table S1. Comparison of Baseline Characteristics Between Included and Excluded Patients

Table S2. Thromboelastographic Measurements According to Index Presentation of Disease (STEMI vs. NSTEMI)

Table S3. Baseline Characteristics of Study Population According to Hypercoagulability and Impaired Fibrinolysis

Table S4. Comparison of Clinical Outcomes at 4 years According to Hypercoagulability and Impaired Fibrinolysis

Supplemental Figures

Figure S1. Determination of Cut-off Value of MA for Predicting Index AMI Presentation

Figure S2. Determination of Cut-off Value of LY30 for Predicting Index AMI Presentation

Figure S3. Incremental Prognostic Value of Thrombogenicity for MACE Risk at 4 Years

Table S1. Comparison of Baseline Characteristics Between Included and Excluded Patients

	Included (N=2,705)	Excluded (N=2,375)	P value
Age, years	65.1 ± 11.9	65.0 ± 11.8	0.708
Men, n (%)	1,938 (71.6)	1,686 (71.0)	0.628
Body mass index, kg/m²	24.3 ± 3.4	24.3 ± 3.4	0.651
Acute myocardial infarction	1,294 (47.8)	1,128 (47.5)	0.829
Risk factors, n (%)			
Current smoking	813 (30.1)	710 (29.9)	0.925
Diabetes mellitus	863 (31.9)	774 (32.6)	0.623
Hypertension	1,429 (52.8)	1,265 (53.3)	0.778
Dyslipidemia	1,459 (53.9)	1,296 (54.6)	0.673

- Prasugrel	169 (6.2)	145 (6.1)	
- Ticagrelor	465 (17.2)	457 (19.2)	
Beta blocker	1,549 (57.3)	1,370 (57.7)	0.784
Angiotensin blocker	1,831 (67.7)	1,604 (67.5)	0.932
Calcium channel blocker	223 (8.2)	170 (7.2)	0.164
Statin	2,542 (94.0)	2,223 (93.6)	0.622

Values are expressed as mean ± standard deviation or number (%).

* Overall, 4,201 patients had information about ankle-brachial index, and peripheral arterial disease was defined as ankle-brachial index ≤0.9 or >1.4.

Abbreviations: ACC = American college of cardiology; AHA = American heart association; AMI = acute myocardial infarction; eGFR = estimated glomerular filtration rate; HDL = high-density lipoprotein; hs-CRP = high sensitivity C-reactive protein; LDL = low-density lipoprotein; LV = left ventricular; PCI = percutaneous coronary intervention; POBA = plain old balloon angioplasty; WBC = white blood count.

Table S2. Thromboelastographic Measurements According to Index Presentation of Disease (STEMI vs. NSTEMI)

	Overall Population (N=1,294)	STEMI (712/1,294, 55.0%)	NSTEMI (582/1,294, 45.0%)	P value
Baseline (at presentation)				
R, min	6.8 ± 4.4	6.3 ± 4.0	7.4 ± 4.9	<0.001
K, min	1.8 ± 1.8	1.6 ± 1.5	2.0 ± 2.0	<0.001
Angle, degree	64.1 ± 13.3	65.8 ± 12.1	62.1 ± 14.3	<0.001
MA, mm	66.5 ± 7.8	67.1 ± 7.4	65.8 ± 8.3	<0.001
MA ≥68 mm	581 (44.9)	336 (47.2)	245 (42.1)	0.076
LY ₃₀ , %	0.9 ± 1.8	0.8 ± 1.7	0.9 ± 1.9	0.499
LY ₃₀ <0.2%	695 (53.7)	378 (53.1)	317 (54.5)	0.661

Values are expressed as mean ± SD or number (%).

Abbreviations: K = coagulation time; LY₃₀ = percentage of the clot that has lysed 30 minutes after the time of maximum amplitude; MA = maximum amplitude; NSTEMI = non-ST-segment elevation acute myocardial infarction; R = reaction time; STEMI = ST-segment elevation acute myocardial infarction.

Table S3. Baseline Characteristics of Study Population According to Hypercoagulability and Impaired Fibrinolysis

	MA <68 mm and LY₃₀ ≥0.2% (Group 1)	MA ≥68 mm or LY₃₀ <0.2% (Group 2)	MA ≥68 mm and LY₃₀ <0.2% (Group 3)	<i>P</i> value

Values are expressed as mean ± standard deviation or number (%).

* Overall, 2200 patients had information about ankle-brachial index, and peripheral arterial disease was defined as ankle-brachial index ≤0.9 or >1.4

Abbreviations: ACC = American college of cardiology; AHA = American heart association; AMI = acute myocardial infarction; eGFR = estimated glomerular filtration rate; HDL = high-density lipoprotein; hs-CRP = high sensitivity C-reactive protein; LDL = low-density lipoprotein; LV = left ventricular; LY₃₀ = percentage of the clot that has lysed 30 minutes after the time of maximum amplitude; MA = maximum amplitude; PCI = percutaneous coronary intervention; POBA = plain old balloon angioplasty; WBC = white blood count.

Table S4. Comparison of Clinical Outcomes at 4 years According to Hypercoagulability and Impaired Fibrinolysis

	Cumulative Incidence	Crude HR (95% CI)	<i>P</i> value	Adjusted HR* (95% CI)	<i>P</i> value
MACE (Cardiovascular death, MI, Stroke)					
1. MA <68 mm and LY ₃₀ ≥0.2%	10.7% (39)	Reference		Reference	
2. MA ≥68 mm or LY ₃₀ <0.2%	18.7% (81)	1.592 (1.085-2.334)	0.017	1.252 (0.833-1.883)	0.279
3. MA ≥68 mm and LY ₃₀ <0.2%	31.2% (52)	2.447 (1.612-3.713)	<0.001	1.781 (1.130-2.808)	0.012
Cardiovascular death					
1. MA <68 mm and LY ₃₀ ≥0.2%	5.1% (15)	Reference		Reference	
2. MA ≥68 mm or LY ₃₀ <0.2%	5.9% (31)	1.515 (0.818-2.808)	0.187	1.308 (0.655-2.613)	0.447
3. MA ≥68 mm and LY ₃₀ <0.2%	7.1% (24)	2.756 (1.443-5.264)	0.002	2.158 (1.028-4.531)	0.042
MI					
1. MA <68 mm and LY ₃₀ ≥0.2%	4.5% (19)	Reference		Reference	
2. MA ≥68 mm or LY ₃₀ <0.2%	11.0% (43)	1.744 (1.015-2.997)	0.044	1.317 (0.742-2.337)	0.347
3. MA ≥68 mm and LY ₃₀ <0.2%	16.8% (24)	2.325 (1.270-4.256)	0.006	1.562 (0.801-3.044)	0.190
Stroke					
1. MA <68 mm and LY ₃₀ ≥0.2%	7.3% (11)	Reference		Reference	
2. MA ≥68 mm or LY ₃₀ <0.2%	5.8% (17)	1.255 (0.587-2.685)	0.558	0.856 (0.387-1.896)	0.701
3. MA ≥68 mm and LY ₃₀ <0.2%	10.2% (12)	2.278 (0.999-5.196)	0.050	1.411 (0.589-3.381)	0.440
BARC type 3 or 5 bleeding					
1. MA <68 mm and LY ₃₀ ≥0.2%	4.8% (17)	Reference		Reference	
2. MA ≥68 mm or LY ₃₀ <0.2%	7.2% (37)	1.660 (0.934-2.950)	0.084	1.341 (0.702-2.562)	0.375
3. MA ≥68 mm and LY ₃₀ <0.2%	4.3% (12)	1.250 (0.595-2.610)	0.559	0.958 (0.422-2.174)	0.918

The cumulative incidence of clinical outcomes is presented as Kaplan-Meier estimates. The number of patients with specific events is also presented in parentheses.

* Multivariable analysis after adjusting for age, sex, diagnosis of acute myocardial infarction, current smoking, hypertension, diabetes mellitus, dyslipidemia, chronic kidney disease, previous PCI, previous stroke, high sensitivity C-reactive protein level, potent P2Y₁₂ inhibitor, beta blocker, angiotensin blocker, and statin.

Prognostic values of models predicting 4-year MACE were compared using Harrell's c-index, NRI, and IDI. Model 1 included the clinical variables of age and sex. There was significant increase in discrimination and reclassification ability with addition of other clinical variables of hypertension, diabetes mellitus, dyslipidemia, current smoker, chronic kidney disease, previous PCI, previous stroke, high sensitivity C-reactive protein level, potent P2Y₁₂ inhibitor, beta blocker, angiotensin blocker, and statin (model 2). Model 3 with thrombogenicity (MA ≥68 mm and LY30 <0.2%) showed further increase in discrimination and reclassification ability for 4-year MACE. The incremental prognostic value of model 3 was consistent when compared with model 2.

Abbreviations: CI = confidence interval; LY₃₀ = percentage of the clot that has lysed 30 minutes after the time of maximum amplitude; MA = maximum amplitude; MACE = major adverse cardiac event; NRI = net reclassification index; IDI = integrated discrimination index; PCI = percutaneous coronary intervention.
